Binary Search Tree

Chapter 12 from textbook

Dynamic Sets

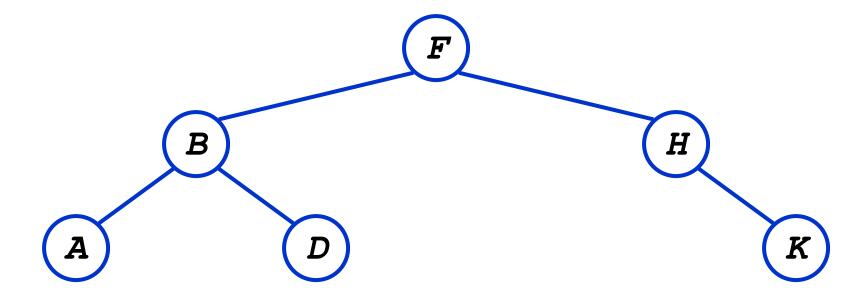

- Next 1-2 lectures we will focus on data structures rather than straight algorithms
- In particular, structures for *dynamic sets*
 - Elements have a *key* and *satellite data*
 - Dynamic sets support *queries* such as:
 - Search(S, k), Minimum(S), Maximum(S),
 Successor(S, x), Predecessor(S, x)
 - They may also support *modifying operations* like:
 - \circ *Insert*(S, x), *Delete*(S, x)

Review: Binary Search Trees

- Binary Search Trees (BSTs) are an important data structure for dynamic sets
- In addition to satellite data, eleements have:
 - key: an identifying field inducing a total ordering
 - left: pointer to a left child (may be NULL)
 - right: pointer to a right child (may be NULL)
 - p: pointer to a parent node (NULL for root)

Review: Binary Search Trees

- BST property: $key[leftSubtree(x)] \le key[x] \le key[rightSubtree(x)]$
- Example:

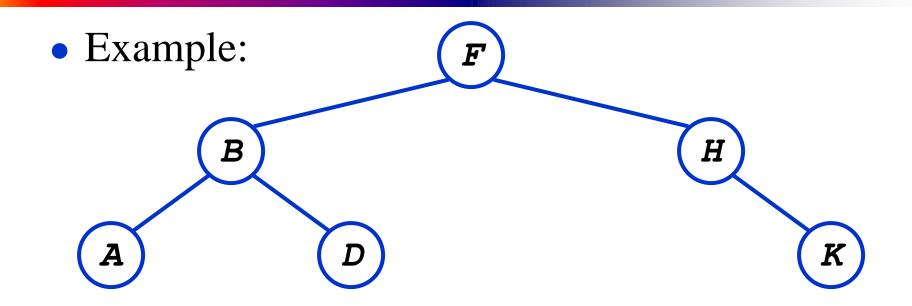

Inorder Tree Walk

• What does the following code do?

```
TreeWalk(x)
    TreeWalk(left[x]);
    print(x);
    TreeWalk(right[x]);
```

- A: prints elements in sorted (increasing) order
- This is called an *inorder tree walk*
 - *Preorder tree walk*: print root, then left, then right
 - *Postorder tree walk*: print left, then right, then root

Inorder Tree Walk

- How long will a tree walk take?
- Inorder walk prints in monotonically increasing order

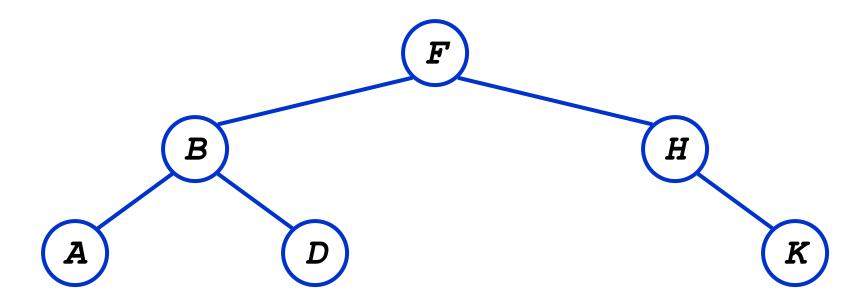

Operations on BSTs: Search

• Given a key and a pointer to a node, returns an element with that key or NULL:

```
TreeSearch(x, k)
   if (x = NULL or k = key[x])
      return x;
   if (k < key[x])
      return TreeSearch(left[x], k);
   else
      return TreeSearch(right[x], k);</pre>
```

BST Search: Example

• Search for *D* and *C*:

Operations on BSTs: Search

• Here's another function that does the same:

```
TreeSearch(x, k)
    while (x != NULL and k != key[x])
        if (k < key[x])
            x = left[x];
        else
            x = right[x];
    return x;</pre>
```

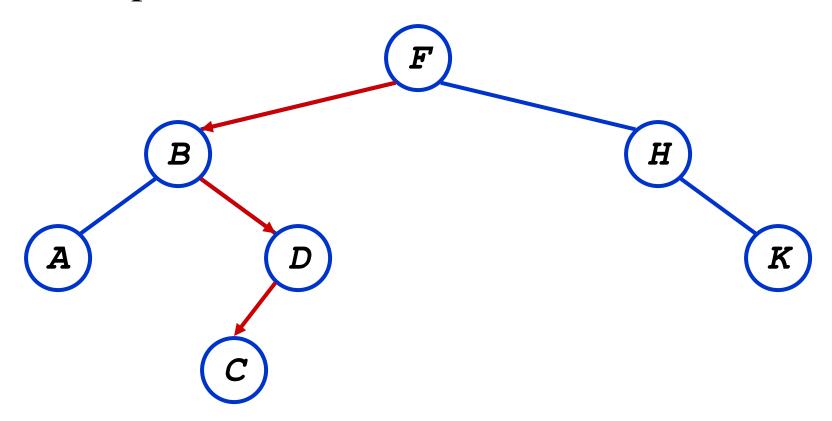

- Which of these two functions is more efficient?
 - Iterative version is more efficient on most computers

Operations of BSTs: Insert

- Adds an element x to the tree so that the binary search tree property continues to hold
- The basic algorithm
 - Like the search procedure above
 - Insert x in place of NULL
 - Use a "trailing pointer" to keep track of where you came from (like inserting into singly linked list)

BST Insert: Example

• Example: Insert *C*

BST Insert:

```
TREE-INSERT (T, z)

1  y = \text{NIL}

2  x = T.root

3  while x \neq \text{NIL}

4  y = x

5  if z.key < x.key

6  x = x.left

7  else x = x.right

8  z.p = y

9  if y = \text{NIL}

10  T.root = z  // tree T was empty

11  elseif z.key < y.key

12  y.left = z

13  else y.right = z
```

BST Search/Insert: Running Time

- What is the running time of TreeSearch() or TreeInsert()?
- A: O(h), where h = height of tree
- What is the height of a binary search tree?
- A: worst case: h = O(n) when tree is just a linear string of left or right children
 - We'll keep all analysis in terms of h for now
 - Later we'll see how to maintain $h = O(\lg n)$

Sorting With Binary Search Trees

Informal code for sorting array A of length n:
 BSTSort (A)

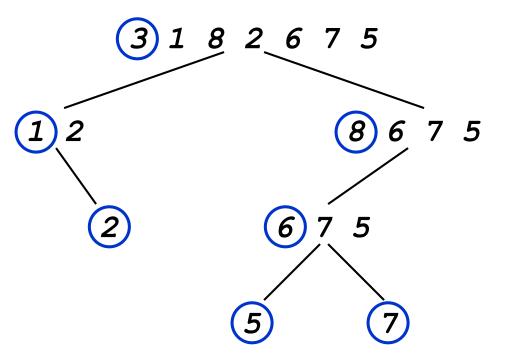

```
for i=1 to n
    TreeInsert(A[i]);
InorderTreeWalk(root);
```

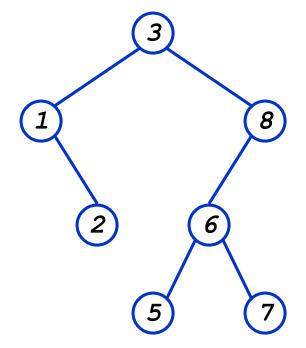

- Argue that this is $\Omega(n \lg n)$
- What will be the running time in the
 - Worst case?
 - Average case? (hint: remind you of anything?)

Sorting With BSTs

- Average case analysis
 - It's a form of quicksort!

```
for i=1 to n
    TreeInsert(A[i]);
InorderTreeWalk(root);
```

Sorting with BSTs

- Same partitions are done as with quicksort, but in a different order
 - In previous example
 - Everything was compared to 3 once
 - Then those items < 3 were compared to 1 once
 - o Etc.
 - Same comparisons as quicksort, different order!
 - Example: consider inserting 5

Sorting with BSTs

- Since run time is proportional to the number of comparisons, same time as quicksort: O(n lg n)
- Which do you think is better, quicksort or BSTsort? Why?

Sorting with BSTs

- Since run time is proportional to the number of comparisons, same time as quicksort: O(n lg n)
- Which do you think is better, quicksort or BSTSort? Why?
- A: quicksort
 - Better constants
 - Sorts in place
 - Doesn't need to build data structure

More BST Operations

- BSTs are good for more than sorting. For example, can implement a priority queue
- What operations must a priority queue have?
 - Insert
 - Minimum
 - Extract-Min

BST Operations: Minimum

- How can we implement a Minimum() query?
- What is the running time?

```
TREE-MINIMUM(x)

1 while x.left \neq NIL

2 x = x.left

3 return x
```

```
TREE-MAXIMUM (x)

1 while x.right \neq NIL

2 x = x.right

3 return x
```

BST Operations: Successor

• For deletion, we will need a Successor() operation

- What is the successor of node 3? Node 15? Node 13?
 - Successor of a node x is the node with the smallest key greater than x.key
- What are the general rules for finding the successor of node x? (hint: two cases)

BST Operations: Successor

- Two cases:
 - x has a right subtree: successor is minimum node in right subtree
 - x has no right subtree: successor is first ancestor of x whose left child is also ancestor of x
 - Intuition: As long as you move to the left up the tree, you're visiting smaller nodes.
- Predecessor: similar algorithm

```
TREE-SUCCESSOR (x)

1 if x.right \neq NIL

2 return TREE-MINIMUM (x.right)

3 y = x.p

4 while y \neq NIL and x == y.right

5 x = y

6 y = y.p

7 return y
```

BST Operations: Delete

- Deletion is a bit tricky
- 3 cases:
 - z has no children:
 - Remove z
 - z has one child:
 - Elevate that child to take z's position in the tree by modifying z's parent to replace z by z's child
 - z has two children:
 - o Find z's successor y and swap z with y
 - Rest of z's original right subtree becomes y's new right subtree and z's left subtree becomes y's new left subtree
 - This can be tricky based on whether y is z's right child

BST Operations: Delete

• We want to delete node z

y is z's successor and rooted at subtree rooted at r, x is y's right child

We replace y by its own right child x, and set y to be r's parent. Then we set y to be q's child and parent of I

BST Operations: Delete

- Transplant replaces one subtree as a child of its parent with another subtree
 - When it replaces the subtree rooted at node u with a subtree rooted at node v
 - Node u's parent becomes node v's parent and u's parent end up having

v as appropriate child

```
TRANSPLANT (T, u, v)

1 if u.p == \text{NIL}

2 T.mot = v

3 elseif u == u.p.left

4 u.p.left = v

5 else u.p.right = v

6 if v \neq \text{NIL}

7 v.p = u.p
```

```
TREE-DELETE (T, z)

1 if z.left == NIL

2 TRANSPLANT (T, z, z.right)

3 elseif z.right == NIL

4 TRANSPLANT (T, z, z.left)

5 else y = TREE-MINIMUM(z.right)

6 if y.p \neq z

7 TRANSPLANT (T, y, y.right)

8 y.right = z.right

9 y.right.p = y

10 TRANSPLANT (T, z, y)

11 y.left = z.left

12 y.left.p = y
```

• Running time of tree delete is O(h), except Tree-Minimum everything is constant time

- Up next: guaranteeing a O(lg n) height tree
 - This ensures all operations on BST can be done in O(lg n) time
